(57) **ABSTRACT**

Methods and apparatus to dynamically control connectivity within VPNs are disclosed. A disclosed example method includes broadcasting, by a route server, a border gateway protocol advertisement as received at the route server; determining a first provider edge router is to be configured for additional connectivity beyond a connectivity defined in a table associated with the first provider edge router, the additional connectivity including an identification of a second provider edge router to which the first provider edge router is to be communicatively coupled; generating a copy of the received border gateway protocol advertisement; modifying the copy of the received border gateway protocol advertisement to facilitate the additional connectivity; and broadcasting the modified copy of the received border gateway protocol advertisement.

METHODS AND APPARATUS TO DYNAMICALLY CONTROL CONNECTIVITY WITHIN VIRTUAL PRIVATE NETWORKS

RELATED APPLICATION

This patent arises from a continuation of U.S. patent application Ser. No. 13/349,305, filed Jan. 12, 2012, now U.S. Pat. No. 8,929,367, which is a continuation of U.S. patent application Ser. No. 12/262,675, filed on Oct. 31, 2008, now U.S. Pat. No. 8,121,118. U.S. patent application Ser. No. 13/349,305 and U.S. patent application Ser. No. 12/262,675 are hereby incorporated herein by reference in their entireties.

FIELD OF THE DISCLOSURE

This disclosure relates generally to virtual private networks (VPNs) and, more particularly, to methods and apparatus to dynamically control connectivity within VPNs.

BACKGROUND

Enterprise customers are increasingly adopting multiprotocol label switching (MPLS) based VPN services to implement a communication network among their respective customer sites via a service provider's network. Such MPLS-based VPNs provide direct any-to-any reachability among an enterprise's customer sites.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic illustration of example communication system constructed in accordance with the teachings of this disclosure.

FIG. 2 illustrates example default intra-VPN connectivity configurations for the example communication system of FIG. 1.

FIG. 3 illustrates an example manner of implementing a route server for the example communication system of FIG. 1.

FIG. 4 illustrates an example data structure that may be used to implement an intra-VPN connectivity database for the example route server of FIG. 3.

FIG. 5 is a flowchart representative of an example process that may be carried out to implement the example route servers of FIGS. 1 and/or 3.

FIG. 6 is a schematic illustration of an example processor platform that may be used and/or programmed to carry out the example process of FIG. 5 and/or to implement any of all of the methods and apparatus disclosed herein.

DETAILED DESCRIPTION

Example methods and apparatus to dynamically control connectivity within virtual private networks (VPNs) are disclosed. A disclosed example route server to control connectivity within a VPN includes a memory to implement an intra-VPN connectivity database, a border gateway protocol (BGP) engine to process BGP advertisements, a network interface to receive a first BGP advertisement from a first provider edge (PE) router associated with the VPN, the first BGP advertisement including a first route target (RT) associated with the first PE router, and an intra-VPN connectivity controller to, in response to the first BGP advertisement, query the database to determine whether the first PE router is to be communicatively coupled to a second PE router of the VPN and when the first and second PE routers of the VPN are

2

to be communicatively coupled, direct the BGP engine to form a second BGP advertisement based on the first BGP advertisement, the second BGP advertisement including a second RT associated with the second PE router.

A disclosed example method includes receiving a first BGP advertisement from a first PE router associated with a VPN, the first BGP advertisement including a first RT associated with the first PE router, automatically querying an intra-VPN connectivity database to determine whether the first PE router is to be communicatively coupled to a second PE router of the VPN, forming a second BGP advertisement based on the first BGP advertisement when the first and second PE routers of the VPN are to be communicatively coupled, the second BGP advertisement including a second RT associated with the second PE router, and broadcasting the second BGP advertisement.

In the interest of brevity and clarity, throughout the following disclosure references will be made to an example multiprotocol label switching (MPLS) based communication system **100** of FIG. 1. However, the methods and apparatus described herein to dynamically control connectivity within VPNs are applicable to other types of networks constructed using other technologies, topologies and/or protocols.

FIG. 1 illustrates the example MPLS-based communication system **100**. To facilitate communication services between a plurality of customer edge (CE) routers, eight of which are designated at reference numerals **105-112**, the example communication system **100** of FIG. 1 includes a service-provider network **115**. While for ease of illustration and discussion, all of the example CE routers **105-112** are associated with a single VPN, the example communication system **100** of FIG. 1 may facilitate communication services for a plurality of VPNs. Moreover, not all of the VPNs implemented by the example communication system **100** need include and/or implement the methods and apparatus to dynamically control intra-VPN connectivity.

To route and/or transport data between and/or among the example CE routers **105-112**, the example service-provider network **115** of FIG. 1 includes a plurality of PE routers, four of which are designated at reference numerals **120, 121, 122** and **123**. The example PE routers **120-123** of FIG. 1 are communicatively coupled to each other via any number and/or type(s) of communication paths (not shown) that allow any particular PE router **120-123** to communicate with at least some, but not necessarily all of, the other PE routers **120-123**.

For each VPN implemented by the service-provider network **115**, each of the example PE routers **120-123** of FIG. 1 has a corresponding VPN routing and forwarding (VRF) table. In the illustrated example of FIG. 1, the PE router **120** has a VRF table **130**, the PE router **121** has a VRF table **131**, the PE router **122** has a VRF table **132**, and the PE router **123** has a VRF table **133**. The example VRF tables **130-133** of FIG. 1 are associated with the VPN communicatively coupling the example CE routers **105-112**. The example VRF tables **130-133** are used by the PE routers **120-123** to route and/or forward a packet received at a particular PE router **120-123** to and/or toward its final destination. In general, when a packet is received at a PE router **120-123** from a CE router **105-112** associated with a particular VPN, the PE router **120-123** uses the final destination specified and/or identified in the packet to perform a query of the VRF table **130-133** associated with that VPN. Based on a result of the query, the PE router **120-123** determines how the packet is to be routed or forwarded within the service provider network **110**, and/or delivered to a particular CE router **105-112**.

By sending, for example, BGP route advertisements, each of the example PE routers **120-123** of FIG. 1 publishes and/or

exports information concerning the CE router(s) **105-112** that are communicatively coupled to the PE router **120-123**. Isolation between different VPNs and/or between different devices of a VPN is achieved via RTs, import policies and/or export policies. Specifically, BGP advertisements and/or routes within a BGP advertisement are tagged with an RT value. The RT that is included in a BGP advertisement is defined by the export policy of the PE router **120-123** that is sending the BGP advertisement. For instance, when the example PE router **120** of FIG. 1 sends a BGP advertisement containing information regarding any of the CE routers **105-107**, the BGP advertisement includes an RT B, as defined by an export policy **135** associated with the VRF table **130**.

Based on received BGP route advertisements, the example PE routers **120-123** of FIG. 1 build, compile, update, maintain and/or construct their respective VRF tables **130-133**. The example PE routers **120-123** import routes in accordance with their associated import policy. In the illustrated example of FIG. 1, when the example PE router **123** receives a BGP advertisement tagged with an RT, the PE router **123** compares the RT contained in the BGP advertisement with its import policy **136**. If the import policy **136** specifies that routes associated with that RT are to be imported, the PE router **123** updates its VRF table **133**. For example, if the BGP advertisement includes an RT G, the PE router **123** would import the routes listed in the BGP advertisement. However, BGP advertisements including other RTs would be ignored.

By configuring the import and export policies of the example VRF tables **130-133**, nominal and/or default routes between the example PE routers **120-123** for the example VPN of FIG. 1 can be controlled, as shown in FIG. 2. For example, if the values A, B, C, D, E, F and G of FIG. 1 are configured to have the same value, then the example VPN of FIG. 1 is configured in the any-to-any topology traditionally utilized within VPNs. If the values A, B, C, D, E, F and G are all different, then no routes between any of PE routers **120-123** for the example VPN of FIG. 1 have been configured and/or enabled. If the values A, C, E, and H have a first value, and the values B, D, F and G have a second value, then the example VPN of FIG. 1 is configured in a hub and spoke topology. In particular, the example PE router **123** would operate as a hub router for the VPN with the other PE routers **120-122** operating as spoke routers.

Returning to FIG. 1, to facilitate sharing of routing information among the example PE routers **120-123**, the example service provider network **110** of FIG. 1 includes any number of route servers, route reflectors, intelligent route reflectors and/or intelligent route service control points, one of which is designated at reference numeral **140**. Because not all of the example PE routers **120-123** are necessarily communicatively coupled in a full mesh topology (for example, when at least one PE router **120-123** does not have a direct communication path to another PE router **120-123**), the example route server **140** of FIG. 1 forwards BGP advertisements among and/or to the PE routers **120-123**. By forwarding each received BGP advertisement, the example route server **140** enables each of the PE routers **120-123** to build, compile and/or construct a VRF table **130-133** that can be used by the PE router **120-123** to route data from any of its communicatively coupled CE routers **105-112** to none, some or all of the CE routers **105-112** communicatively coupled to other PE routers **120-123**, even if such routing of data requires use of one or more intervening PE routers **120-123**.

To dynamically control communication within the example VPN of FIG. 1 without having to reconfigure and/or change import and/or export policies of a VRF table **130-133**, the example route server **140** of FIG. 1 forms a copy of each

BGP advertisement that it receives, modifies the copy of the received BGP advertisement, and sends and/or broadcasts the modified BGP advertisement. For example, when the example PE router **120** is to be communicatively coupled to the example PE router **122** for a particular VPN and the example route server **140** of FIG. 1 receives a BGP advertisement **150** that includes the RT B associated with the export policy **135** of the VRF table **130**, the example route server **140** broadcasts a version **151** of the BGP advertisement **150** that includes an RT E associated with an import policy **155** of the VRF table **132**. Likewise, when the example route server **140** receives a BGP advertisement **152** that includes an RT F associated with an export policy **156** of the VRF table **132**, the example route server **140** broadcasts a version **153** of the BGP advertisement **152** that includes an RT A associated with an import policy **157** of the VRF table **130**. When a particular PE router **120-123** is not to have additional connectivity within a VPN beyond that defined by the import and/or export policy of the PE router **120-123**, the route server **140** forwards the originally received BGP advertisements **150** and **152** without making, modifying and/or sending a copy of the received BGP advertisements **150** and/or **152**.

Intra-VPN connectivity enabled by the example route server **140** is in addition to any intra-VPN connectivity defined by the import and/or export policies of the VRF tables **130-132**. For example, if the values A, B, C, D, E, F and G are all different, the route server **140** is the sole enabler for connectivity within the example VPN of FIG. 1. However, if the values A, C, E, and H have a first value, and the values B, D, F and G have a second value thereby enabling a hub and spoke topology with the PE router **123** operating as a hub router, the example route server **140** can be used to dynamically enable additional connectivity between the spoke PE routers **120-122**.

To determine whether PE routers **120-123** are to have additional connectivity within a VPN beyond that defined by their respective import and export policies, the example route server **140** of FIG. 1 queries an intra-VPN connectivity database **305** (FIG. 3). As described below in connection with FIGS. 3 and 4, a user and/or computer **310** can dynamically and/or selectively configure connectivity within a VPN by configuring the intra-VPN connectivity database **305**. An example manner of implementing the example route server **140** of FIG. 1 is described below in connection with FIG. 3.

While an example communication system has been illustrated in FIG. 1, one or more of the interfaces, data structures, elements, processes and/or devices illustrated in FIG. 1 may be combined, divided, re-arranged, omitted, eliminated and/or implemented in any other way. Further, the example PE routers **120-123** and/or the example route server **140** of FIG. 1 may be implemented by hardware, software, firmware and/or any combination of hardware, software and/or firmware. Thus, for example, any of the example PE routers **120-123** and/or the example route server **140** may be implemented by one or more circuit(s), programmable processor(s), application specific integrated circuit(s) (ASIC(s)), programmable logic device(s) (PLD(s)) and/or field programmable logic device(s) (FPLD(s)), etc. Further still, a communication system may include interfaces, data structures, elements, processes and/or devices instead of, or in addition to, those illustrated in FIG. 1 and/or may include more than one of any or all of the illustrated interfaces, data structures, elements, processes and/or devices.

FIG. 3 illustrates an example manner of implementing the example route server **140** of FIG. 1. To implement one or more interfaces to the example PE routers **120-123**, the example route server **140** of FIG. 3 includes any number

5

and/or type(s) of network interfaces, one of which is designated at reference numeral **315**.

To send, receive and process BGP route advertisements, the example route server **140** of FIG. **3** includes a multi-protocol BGP engine **320**. When a BGP route advertisement is received from a PE router **120-123** via the example network interface **315**, the example multi-protocol BGP engine **320** of FIG. **3** forwards the received BGP route advertisement to the other PE routers **120-123**. The example multi-protocol BGP engine **320** also queries an intra-VPN connectivity controller **325** to determine whether one or more modified copies of the received BGP router advertisement are to be broadcast.

To control connectivity within a VPN, the example route server **140** of FIG. **3** includes the example intra-VPN connectivity controller **325**. When queried by the example multi-protocol BGP engine **320**, the example intra-VPN connectivity controller **325** of FIG. **3** queries the example intra-VPN connectivity database **305** to determine whether BGP advertisements associated with a first RT are to be re-broadcast with one or more additional RT. When intra-VPN connectivity beyond that defined by import and/or export policies is to be enabled for a particular RT, the example intra-VPN connectivity controller **325** returns to the multi-protocol BGP engine **320** the one or more additional RTs with which the received BGP route advertisement is to be re-broadcast.

In response to the one or more additional RTs, the example multi-protocol BGP engine **320** of FIG. **3** creates one or more corresponding copies of the received BGP advertisement, modifies the original RT to correspond with a respective one of the one or more additional RTs, and broadcasts the modified copy(-ies) of the received BGP advertisement.

Intra-VPN connectivity configuration information may be stored in the example intra-VPN connectivity database **305** using any number and/or type(s) of data structures. An example data structure that may be used to implement the example shared resource control access database **305** of FIG. **3** is described below in connection with FIG. **4**. The example intra-VPN connectivity database **305** may be stored using any number and/or type(s) of memory(-ies), memory device(s) and/or storage device(s).

To allow the user and/or computer **310** to configure intra-VPN connectivity for a VPN, the example route server **140** of FIG. **3** includes any number and/or type(s) of user interface modules, one of which is designated at reference numeral **330**. The example user **310** of FIG. **3** may be associated with a particular VPN, and/or be associated with an operator of the service-provider network **115**. The example user interface module **330** of FIG. **3** enables the user **310** to interact with the example intra-VPN connectivity controller **325** to update the database **305** to configure connectivity within a VPN. In some examples, intra-VPN connectivity can be configured differently for different periods of time, temporarily configured with an expiration time, and/or automatically re-configured in response to a triggering event. For instance, during business hours there may be full connectivity within a VPN, with the VPN reverting to a nominal hub-and-spoke topology during non-business hours. Additionally or alternatively, if a virus and/or security anomaly is detected, connectivity within a VPN may be restricted and/or blocked to reduce the likelihood of damage. Example user interface modules **330** include, but are not limited to, a web-based interface, a voice activated response system and/or an application programming interface accessible to another computer system **310**.

While an example route server **140** has been illustrated in FIG. **3**, one or more of the interfaces, data structures, elements, processes and/or devices illustrated in FIG. **3** may be combined, divided, re-arranged, omitted, eliminated and/or

6

implemented in any other way. Further, the example intra-VPN connectivity database **305**, the example network interface **315**, the example multi-protocol BGP engine **320**, the example intra-VPN connectivity controller **325**, the example user interface module **330**, and/or, more generally, the example route server **140** of FIG. **3** may be implemented by hardware, software, firmware and/or any combination of hardware, software and/or firmware. Thus, for example, any or the example intra-VPN connectivity database **305**, the example network interface **315**, the example multi-protocol BGP engine **320**, the example intra-VPN connectivity controller **325**, the example user interface module **330**, and/or, more generally, the example route server **140** may be implemented by one or more circuit(s), programmable processor(s), ASIC(s), PLD(s) and/or FPLD(s), etc. Further still, a route server may include interfaces, data structures, elements, processes and/or devices instead of, or in addition to, those illustrated in FIG. **3** and/or may include more than one of any or all of the illustrated interfaces, data structures, elements, processes and/or devices.

FIG. **4** illustrates an example data structure that may be used to implement the example intra-VPN connectivity database **305** of FIG. **3**. The example data structure of FIG. **4** includes a plurality of entries for respective ones of pairs of RTs, one of which is designated at reference numeral **410**. Each of the example entries **410** is associated with a particular combination of RTs. For instance, the example entry **410** is associated with a combination of RT F and RT G.

To identify whether communication between the VRFs **130-133** associated with a particular combination of RTs is currently enabled, each of the example entries **410** contains one or more values, flags, rules, criteria and/or strings that represent whether the example route server **140** is to cross-communicate BGP advertisements between the RTs associated with the entry **410**. Example entries **410** include, but are not limited to, a flag that indicates that connectivity between the RTs is unconditionally enabled, a time of day range that specifies when connectivity is enabled, a condition when connectivity is enabled, and/or a condition when connectivity is disabled. In some examples, the example entries **410** of FIG. **4** each contain a simple flag to indicate whether the example route server **140** is to cross-communicate BGP advertisements between the RTs associated with the entry **410**. In such examples, the example user and/or computer **310** (FIG. **3**) is responsible for configuring the example intra-VPN connectivity database **305** in response to one or more of conditions, time of day, day of week and/or triggering events.

While an example data structure that may be used to implement the example intra-VPN connectivity database **305** of FIG. **3** is illustrated in FIG. **4**, the example data structure of FIG. **4** may be implemented using any number and/or type(s) of other and/or additional entries, fields and/or data. Further, the entries, fields and/or data illustrated in FIG. **4** may be combined, divided, re-arranged, eliminated and/or implemented in any way. Further still, the example data structures may include entries, fields and/or data in addition to, or instead of, those illustrated in FIG. **4**, and/or may include more than one of any or all of the illustrated entries, fields and/or data. Moreover, the example data structure **305** of FIG. **4** may be queried using any additional and/or alternative methods.

FIG. **5** illustrates a flowchart representative of an example process that may be carried out to implement any of the example route servers **140** of FIGS. **1** and/or **3**. The example process of FIG. **5** may be carried out by a processor, a controller and/or any other suitable processing device. For example, the example process of FIG. **5** may be embodied in

coded instructions stored on any tangible computer-readable medium such as a flash memory, a compact disc (CD), a digital versatile disc (DVD), a floppy disk, a read-only memory (ROM), a random-access memory (RAM), a programmable ROM (PROM), an electronically-programmable ROM (EPROM), and/or an electronically-erasable PROM (EEPROM), an optical storage disk, an optical storage device, magnetic storage disk, a magnetic storage device, and/or any other medium which can be used to carry or store program code and/or instructions in the form of machine-accessible instructions or data structures, and which can be accessed by a processor, a general-purpose or special-purpose computer, or other machine with a processor (e.g., the example processor platform P100 discussed below in connection with FIG. 6). Combinations of the above are also included within the scope of computer-readable media. Machine-accessible instructions comprise, for example, instructions and/or data that cause a processor, a general-purpose computer, special-purpose computer, or a special-purpose processing machine to implement one or more particular processes. Alternatively, some or all of the example process of FIG. 5 may be implemented using any combination(s) of ASIC(s), PLD(s), FPLD(s), discrete logic, hardware, firmware, etc. Also, some or all of the example process of FIG. 5 may instead be implemented manually or as any combination of any of the foregoing techniques, for example, any combination of firmware, software, discrete logic and/or hardware. Further, many other methods of implementing the example operations of FIG. 5 may be employed. For example, the order of execution of the blocks may be changed, and/or one or more of the blocks described may be changed, eliminated, sub-divided, or combined. Additionally, any or all of the example process of FIG. 5 may be carried out sequentially and/or carried out in parallel by, for example, separate processing threads, processors, devices, discrete logic, circuits, etc.

The example process of FIG. 5 begins with the example user interface module 330 of FIG. 3 determining whether updated intra-VPN connectivity configuration information has been received (block 505). If updated intra-VPN connectivity configuration information has been received (block 505), the example intra-VPN connectivity controller 325 makes corresponding updates to the example intra-VPN connectivity database 305 (block 510). Control then returns to block 505.

If updated intra-VPN connectivity configuration information was not received (block 505), the example multi-protocol BGP engine 320 of FIG. 3 determines whether a BGP advertisement was received via the example network interface 315 (block 515). If a BGP advertisement was not received (block 515), control returns to block 505.

If a BGP advertisement was received (block 515), the multi-protocol BGP engine 320 broadcasts the received BGP advertisement (block 520). The multi-protocol BGP engine 320 queries the intra-VPN connectivity controller 325 to determine whether modified copies of the received BGP advertisement are to be broadcast (block 525). If the intra-VPN connectivity controller 325 determines that no modified copies of the received BGP advertisement are to be broadcast (block 525), control returns to block 505.

If based on a query of the example intra-VPN connectivity database 305, the intra-VPN connectivity controller 325 returns one or more RTs (block 525), the multi-protocol BGP engine 320 creates one or more corresponding copies of the received BGP advertisement (block 530), modifies the RT of the copy(-ies) with respective ones of the returned RT(s) (block 535), and broadcasts the modified BGP advertisement (s) (block 540). Control then returns to block 505.

FIG. 6 is a schematic diagram of an example processor platform P100 that may be used and/or programmed to implement any of the example route servers 140 of FIGS. 1 and/or 2. For example, the processor platform P100 can be implemented by one or more general-purpose processors, processor cores, microcontrollers, etc.

The processor platform P100 of the example of FIG. 6 includes at least one general purpose programmable processor P105. The processor P105 executes coded instructions P110 and/or P112 present in main memory of the processor P105 (e.g., within a RAM P115 and/or a ROM P120). The processor P105 may be any type of processing unit, such as a processor core, a processor and/or a microcontroller. The processor P105 may execute, among other things, the example process of FIG. 5 to implement the example methods and apparatus described herein.

The processor P105 is in communication with the main memory (including a ROM P120 and/or the RAM P115) via a bus P125. The RAM P115 may be implemented by DRAM, SDRAM, and/or any other type of RAM device, and ROM may be implemented by flash memory and/or any other desired type of memory device. Access to the memory P115 and the memory P120 may be controlled by a memory controller (not shown). One or both of the example memories P115 and P120 may be used to implement the example intra-VPN connectivity database 305 of FIG. 3.

The processor platform P100 also includes an interface circuit P130. The interface circuit P130 may be implemented by any type of interface standard, such as an external memory interface, serial port, general-purpose input/output, etc. One or more input devices P135 and one or more output devices P140 are connected to the interface circuit P130. The input devices P135 and/or output devices P140 may be used to, for example, implement the network interface 315 of FIG. 3.

Although certain example methods, apparatus and articles of manufacture have been described herein, the scope of coverage of this patent is not limited thereto. On the contrary, this patent covers all methods, apparatus and articles of manufacture fairly falling within the scope of the appended claims either literally or under the doctrine of equivalents.

What is claimed is:

1. A method, comprising:

broadcasting, with a route server, a border gateway protocol advertisement as received at the route server; determining, with the route server, a first provider edge router is to be configured for additional connectivity beyond a connectivity defined in a table associated with the first provider edge router, the additional connectivity including an identification of a second provider edge router to which the first provider edge router is to be communicatively coupled; generating, with the route server, a copy of the received border gateway protocol advertisement; modifying, with the route server, the copy of the received border gateway protocol advertisement to facilitate the additional connectivity; and broadcasting, with the route server, the modified copy of the received border gateway protocol advertisement.

2. The method of claim 1, wherein the modifying of the copy of the received border gateway protocol advertisement includes changing a route target of the border gateway protocol advertisement as received at the route server to correspond to the additional connectivity.

3. The method of claim 1, further including enabling a user to define a condition to control when the first provider edge router is to be configured for the additional connectivity.

9

4. The method of claim 3, wherein the condition includes at least one of a period of time, a security status, and a triggering event.

5. The method of claim 1, further including:

determining the first provider edge router is not to be configured for the additional connectivity; and

when the first provider edge router is not to be configured for the additional connectivity, not generating the copy of the received border gateway protocol advertisement, wherein the generating of the copy, the modifying of the copy, and the broadcasting of the modified copy are in response to the determining that the first provider edge router is to be configured for the additional connectivity.

6. The method of claim 1, wherein the determining that the first provider edge router is to be configured for the additional connectivity is based on a result from querying a user-configurable database.

7. The method of claim 1, wherein the table includes a virtual private network routing and forwarding table.

8. A route server, comprising:

a memory including machine readable instructions; and a processor to execute the instructions to cause the route server to perform operations including:

broadcasting a border gateway protocol advertisement as received at the route server;

determining a first provider edge router is to be configured for additional connectivity beyond a connectivity defined in a table associated with the first provider edge router, the additional connectivity including an identification of a second provider edge router to which the first provider edge router is to be communicatively coupled;

generating a copy of the received border gateway protocol advertisement;

modifying the copy of the received border gateway protocol advertisement to facilitate the additional connectivity; and

broadcasting the modified copy of the received border gateway protocol advertisement.

9. The route server of claim 8, wherein the modifying of the copy of the received border gateway protocol advertisement includes changing a route target of the border gateway protocol advertisement as received at the route server to correspond to the additional connectivity.

10. The route server of claim 8, wherein the operations further include enabling a user to define a condition to control when the first provider edge router is to be configured for the additional connectivity.

11. The route server of claim 10, wherein the condition includes at least one of a period of time, a security status, and a triggering event.

12. The route server of claim 8, wherein the operations further include:

determining the first provider edge router is not to be configured for the additional connectivity; and

when the first provider edge router is not to be configured for the additional connectivity, not generating the copy

10

of the received border gateway protocol advertisement, wherein the generating of the copy, the modifying of the copy, and the broadcasting of the modified copy are in response to the determining that the first provider edge router is to be configured for the additional connectivity.

13. The route server of claim 8, wherein the determining the first provider edge router is to be configured for the additional connectivity is based on a result from querying a user-configurable database.

14. The route server of claim 8, wherein the table includes a virtual private network routing and forwarding table.

15. A tangible machine readable storage device including instructions that, when executed, cause a machine to perform operations comprising:

broadcasting, by a route server, a border gateway protocol advertisement as received at the route server;

determining whether a first provider edge router is to be configured for additional connectivity beyond a connectivity defined in a table associated with the first provider edge router, the additional connectivity including an identification of a second provider edge router to which the first provider edge router is to be communicatively coupled;

generating a copy of the received border gateway protocol advertisement;

modifying the copy of the received border gateway protocol advertisement to facilitate the additional connectivity; and

broadcasting the modified copy of the received border gateway protocol advertisement.

16. The storage device of claim 15, wherein the modifying of the copy of the received border gateway protocol advertisement includes changing a route target of the border gateway protocol advertisement as received at the route server to correspond to the additional connectivity.

17. The storage device of claim 15, wherein the operations further include enabling a user to define a condition to control when the first provider edge router is to be configured for the additional connectivity.

18. The storage device of claim 17, wherein the condition includes at least one of a period of time, a security status, and a triggering event.

19. The storage device of claim 15, wherein the operations further include:

determining the first provider edge router is not to be configured for the additional connectivity; and

when the first provider edge router is not to be configured for the additional connectivity, not generating the copy of the received border gateway protocol advertisement, wherein the generating of the copy, the modifying of the copy, and the broadcasting of the modified copy are in response to the determining that the first provider edge router is to be configured for the additional connectivity.

20. The storage device of claim 15, wherein the table includes a virtual private network routing and forwarding table.
